Fibromyalgia

What is fibromyalgia?
Fibromyalgia is a chronic condition that affects the muscles, tendons and ligaments (bands of tissue that connect bone to bone). This can result in fatigue, widespread and extreme sensitivity to pain.

Fibromyalgia is known as a syndrome because it is a collection of symptoms rather than a specific disease process. The symptoms of fibromyalgia can vary from person to person and other than pain and fatigue symptoms may often include:

- Non-refreshing sleep
- Waking up tired and stiff
- Headaches ranging from ordinary types to migraine
- Irritable bowel
- Frequent diarrhoea or constipation, sometimes accompanied by gas in the abdomen or nausea
- Cognitive disturbances including lack of concentration and word mix-up
- Clumsiness and dizziness
- Sensitivity to changes in the weather and to noise, bright lights, smoke and other environmental factors
- Allergies

The symptoms can come and go over time. Sometimes long periods of time without any symptoms are possible. However, it is unlikely that they will ever permanently disappear altogether.

Fibromyalgia used to be known as fibrositis, which literally means inflammation of the muscles and soft tissue. The condition was renamed fibromyalgia after studies found that there is no inflammation or nerve injury.

Fibromyalgia is not life-threatening and does not reduce life expectancy. Learning to manage the condition is the most successful way of dealing with fibromyalgia. A combination of warmth, rest, exercise and reducing tensions can enable people with fibromyalgia to maintain a productive life.

What causes fibromyalgia?
The actual cause of fibromyalgia has not yet been identified. Fibromyalgia often develops after some sort of trauma that seems to act as a trigger. This could be a fall, car accident, a viral infection, childbirth, an operation or an emotional event. Sometimes however, the condition begins without any obvious triggering event.
Fibromyalgia is not new, but for most of the last century it was difficult to diagnose because the condition cannot be identified using standard laboratory tests or x-rays. In 1990 an international committee published requirements for the diagnosis of Fibromyalgia that are now widely accepted. These are:

Relevant patient’s history and two main symptoms:

1. Widespread pain for more than three months together with

2. Pain in at least 11 out of 18 specific tender point sites when they are pressed.

“Widespread pain” means pain above and below the waist and on both sides of the body. The “tender points”, or spots of extreme tenderness, are rarely noticed by the patient until they are pressed.

What is the treatment for fibromyalgia?

At the present time treatment for fibromyalgia aims to manage pain and fatigue and improve sleep. Sometimes medications can help. The best way to cope with fibromyalgia is to use a number of techniques that ease symptoms as much as possible.

Relaxation is one technique that works really well for almost everybody with fibromyalgia. It reduces tension in the mind and body right away. The results are calming for all of the symptoms especially for the pain.

Pacing your activities, regularly stretching and doing light exercise are other beneficial techniques. All these techniques will be discussed with you by the nurses within the Pain Clinic.

Psychological therapies can also be helpful to enable some people to cope with this condition and to take an active part in their own treatment.

Other sources of information and support

There are several websites on the internet which may provide useful information and support. Below are just a few.

- www.fibromyalgia-associationuk.org
- www.fibroaction.org
- www.fmnetnews.com
- www.menwithfibro.org
- www.fibropals.co.uk

Addenbrooke’s is not responsible for and does not endorse any of the content within these websites.
We are now a smoke-free site: smoking will not be allowed anywhere on the hospital site. For advice and support in quitting, contact your GP or the free NHS stop smoking helpline on 0800 169 0 169.
